Triethanolamine Carcinogenicity:

The national Toxicology Program (NTP) has conducted a chronic (lifetime) dermal exposure study in rats and mice exposed to Triethanolamine (TEA). In this case, female rats dermally exposed to TEA concentrations of up to 250 milligrams (mg) of TEA per kilogram (kg) of body weight (mg/kg/day) did not show an increased incidence of tumors. However, male rats dermally exposed to TEA concentrations of 32 to 125 mg/kg/day showed a marginal increase in kidney tumors (renal tubule cell adenomas). Male mice dermally exposed to TEA concentrations of 200 to 2000 mg/kg/day showed a marginal increase in liver tumors (hepatocellular adenomas and hepatoblastomas). Female mice exposed to 100 to 1000 mg/kg/day showed an increase incidence of liver tumors (hepatocellular adenoma and carcinoma). In the study report, NTP has concluded that there is "no evidence: of cancer in female rats, "equivocal evidence" of kidney cancer in male rats, and due to infection of the study animals with *Helicobacter hepaticus* is a bacterial known to cause liver cancers in infected animals.

The NTP has sponsored a repeat study in mice that are believed to be free of *Helicobacter* infection. This study is currently underway.
